

1. The first step is to identify the variables that are likely to influence the outcome variable. In this case, the variables are the number of hours worked per week, the number of children in the household, and the number of children under the age of 6.

2. The second step is to estimate the parameters of the model. This is done by using the method of least squares, which minimizes the sum of the squared residuals.

3. The third step is to test the hypotheses. This is done by using the F-test, which tests the null hypothesis that the coefficients are equal to zero.

4. The fourth step is to interpret the results. This is done by looking at the coefficients and the p-values.

5. The fifth step is to write the conclusion. This is done by summarizing the findings of the study.
